Site Details

My live ward activity board is at <https://brynbing03.github.io/wdd331/unit-1/custom-properties/index.html> and the source code is at <https://github.com/Brynbing03/wdd331.git>.

Reflections

You wrote all of your CSS using native nesting. Compare the experience to writing flat, non-nested CSS. Where did nesting make your stylesheet clearer, and was there a point where it started to feel like too much? How would you decide where to stop nesting in a larger project?

I actually really liked using native nesting because I felt like it made my CSS a little more organized. It is going to take some getting used to, but so far I am really liking it. Instead of writing separate selectors for every little thing, I was able to keep styles for things like the card title, tag, and links inside the main card section. I feel like this made it easier for me to see which styles belonged together. I think that if I went too deep with the nesting, I would get really confused, so I will have to take it a little at a time. I think that in a larger project, I would only nest styles that were clearly supposed to be together, like in the same section or component, and then stop when it starts making the CSS file hard to read. I think it is really nice so far though! :)

Your stylesheet derives values from tokens using `calc()` and `clamp()`. Pick one of those derived values and explain what would happen if you changed the base token it depends on. How many places in your stylesheet would be affected, and why does that matter on a team?

One value I used with `calc()` was the spacing between my cards. I used my `--space-md` token and multiplied it by two to create the gap between the cards. Right now `--space-md` is set to `1rem`, so the gap between my cards is `2rem`. If I changed that base token to `1.5rem`, the card gap would automatically change to `3rem`. I hope I used this correctly. I also use `--space-md` in 6 different places throughout my CSS, so changing that one token would affect all 6 places if I understand it correctly. I think this is really helpful because instead of going through my whole CSS file and changing the spacing one by one, I can change it in one place. This would also be really useful when working on a team because everyone could use the same tokens and keep the spacing consistent throughout the website so it would look really good!

Look at your finished ward activity board at a narrow mobile width and a wide desktop width. Describe one specific thing that `clamp()` or your responsive layout handled automatically that would have required a media query in traditional CSS:

I actually really like `clamp()`. I am still trying to get a solid grasp on it, but I think I am getting there. One thing that I noticed was how many cards automatically changed depending on the screen being a different size. On a wider computer screen, the cards were displayed in three columns, but when I made the browser really narrow like how a phone might be, they automatically moved into one column. I thought this was really cool because I did not have to create a separate media query to tell the cards when to move, which was really nice. The responsive grid handled it for me based on the space that was available. This made the page work well on different screen sizes without having to add a bunch of extra CSS. I think it is pretty slick how it works.
